THE STABLE TOPOLOGY OF MODULI SPACES OF PERIODIC INSTANTONS

By

Hiromichi MATSUNAGA

1. Introduction and statement of the result

Let M be a smooth 4-manifold which admits an open subset K with one end N and an open submanifold W_0 with two ends N_-, N_+ . W_1, W_2, \dots denote copies of W_0 . The 4-manifold M will be called end-periodic if it admits a decomposition $M = K \cup_N W_0 \cup_N W_1 \cup \dots$, where $N \subset K$ is identified with the end N_- of W_0 and the end N_+ of W_0 is identified with the end N_- of W_1 and so on. Let Y be the compact oriented 4-manifold which is obtained from W_0 by identifying the two ends. The manifold Y has a Z -cover $\tilde{Y} = \dots_N W_{-1} \cup_N W_0 \cup_N W_1 \dots$ with projection $\pi: \tilde{Y} \rightarrow Y$. A geometric object on M , a vector bundle, a connection, a differential operator, a Riemannian metric etc. will be called end-periodic if its restriction on $\text{End}M = W_0 \cup_N W_1 \dots$ is the pull back by π of an object on Y . By making choose a smooth function $s: W_0 \rightarrow [0, 1]$ such that $s|_{N_-} = 0$ and $s|_{N_+} = 1$, we obtain a smooth step function t on M such that $t(x) = n + s(x)$ if $x \in W_n$.

Let $P \rightarrow M$ be an end-periodic principal $SU(2)$ -bundle, and A_0 be an end-periodic connection on P which is gauge equivalent over $\text{End}M$ to the product connection on $\text{End}M \times SU(2)$. Then by the lemma 7.1 in [7]

$$l = (1/8\pi^2) \int_M \text{tr}(F_{A_0} \wedge F_{A_0})$$

is an integer, where $\text{tr}(\)$ is the trace on the adjoint representation of the group $SU(2)$. Let $E \rightarrow M$ be an end-periodic vector bundle which is associated to the principal bundle $P \rightarrow M$. Put $L^2_{\text{loc}}(E) = \{\text{section } u; u \in L^2(E|_A) \text{ for every measurable } A \subset M\}$, where we assume that the set A has a finite measure, and denote by $\|\cdot\|_{A_0}$ the norm by the covariant derivative $\nabla_{A_0}: C_0^\infty(E) \rightarrow C_0^\infty(E \otimes T^*M)$ of compactly supported smooth sections, further $\nabla_{A_0}^{(j)}$ denotes the j -times iterated derivative $\nabla_{A_0} \dots \nabla_{A_0}$. For $\delta > 0$, put

$$\mathcal{L}_k(\delta) = \{A_0 + a; a \in L^2_{5, \text{loc}}(adP \otimes T^*M) \text{ with norm } \|a\|_{A_0} < \infty\},$$

Received May 19, 1994. Revised December 1, 1994.

where $\|a\|_{A_0} = \int_M e^{t\delta} \sum_{j=0}^5 \|\nabla_{A_0}^{(j)} a\|^2$ and define the small gauge group $\mathcal{G}'_k(\delta) = \{h \in L^2_{6,\text{loc}}(\text{Aut}P); \|\nabla_{A_0} h\|_{A_0} < \infty, \text{ and tends to the identity at infinity}\}$, where we have used the adjoint representation $\text{ad}: SU(2)/Z_2 \rightarrow \text{End}(\mathfrak{su}(2))$ and the embedding $C^\infty(P \times_{\text{ad}} SU(2)/Z_2) \rightarrow C^\infty(P \times_{\text{ad}} \text{End}(\mathfrak{su}(2)))$.

Let $\mathcal{A}_k^*(\delta) \subset \mathcal{A}_k(\delta)$ denote the subset of irreducible connections, and g_0 be an end-periodic metric on the tangent bundle TM and \mathcal{C} be the set of asymptotically periodic metrics ((6.1) in [7]). Consider a \mathcal{G}_k , equivariant map

$$\mathcal{P}: \mathcal{A}_k(\delta) \times \mathcal{C} \ni (A, \phi) \rightarrow P_-(g_0)(\phi^{-1})^* F_A \in L^2_{4,\text{loc}}(\text{ad}P \otimes P_- \Lambda^2 T^*M),$$

where P_- denotes the projection to the anti-self dual part. Let $\bar{\pi}': \mathcal{M}'_k = \mathcal{P}^{-1}(0)/\mathcal{G}'_k \rightarrow \mathcal{C}$ be the projection. Put $\mathcal{M}(\phi)'_k = \bar{\pi}'^{-1}(\phi)$. According to the lemmas 5.3, 5.8 and 8.4 in [7], there exists a positive number $\delta_* > 0$ such that for any $\delta, 0 < \delta < \delta_*$, $\mathcal{M}'_k(\phi) \cap (\mathcal{A}_k^*(\delta)/\mathcal{G}'_k(\delta))$ is a smooth manifold. Ω^3_k denotes the 3-fold iterated loop space of mappings of degree k . In this paper we consider the case of the manifold $M = S^1 \times R^3$ which has been considered as an end-periodic manifold, $M' = S^1 \times D^{3/2} \cup (S^1 \times S^2 \times (1, 3)) \cup (S^1 \times S^2 \times (2, 4)) \cup \dots$ (Proposition 1 in [1]). Now we have the following result which is proved in Appendix.

PROPOSITION. The manifold M' admits an end-periodic metric.

Then the main result in this article is

THEOREM. There exists a map $\mathcal{M}'_k(\phi) \rightarrow \Omega^3_k(S^3)$ which induces a surjection of homology groups

$$H_q(\mathcal{M}'_k(\phi)) \rightarrow H_q(\Omega^3_k(S^3)) \quad \text{for } q \leq [k/2].$$

In the previous paper [1] we have discussed the moduli space of self-dual, asymptotically periodic instantons. There we have used the gauge group $\mathcal{G}_k(\delta) = \{h \in L^2_{6,\text{loc}}(\text{Aut}P); \|\nabla_{A_0} h\|_{A_0} < \infty\}$ instead of the small gauge group $\mathcal{G}'_k(\delta)$. Let $\bar{\pi}: \mathcal{M}_k = \mathcal{P}^{-1}(0)/\mathcal{G}_k(\delta) \cap (\mathcal{A}_k^*(\delta))/\mathcal{G}_k \rightarrow \mathcal{C}$ be the projection and put $\mathcal{M}_k(\phi) = \bar{\pi}^{-1}(\phi)$. Then we have a principal $SO(3)$ -bundle $\mathcal{M}'_k(\phi) \cap (\mathcal{A}_k^*(\delta)/\mathcal{G}'_k(\delta)) \rightarrow \mathcal{M}_k(\phi)$.

We prove the main theorem in the sections 2 and 3. Our main tools are periodic instantons due to Harrington-Shepard, Atiyah-Jones diagram and Taubes' existence theorem ([3], [2], [8]).

I am grateful to Doctor Yamaguchi K. for his indication of the usefulness of the proposition (A.1) in [6], and wish to thank the referee for his kind advices.

2. Deformation of Harrington-Shepard's periodic instantons

We abbreviate hyperbolic functions as follows:

$$\text{ch} = \cosh, \text{ and } \text{sh} = \sinh.$$

Let r be the distance from the source to a point in R^3 and $\tau \in [0, 2\pi]$.

Then Harrington-Shepard's periodic solution is given by

$$\phi = 1 + \frac{1}{r} \cdot \frac{\text{shr}}{\text{chr} - \cos \tau} \quad ([3]).$$

Let t be the smooth step function in the selection 1, and f be a smooth cut off function such that $f|_{K-N=1}$ and $\{\text{support } f\} \subset K$. We put

$$\tilde{\phi}(\delta) = 1 + \frac{1}{r} \cdot \frac{\text{shr}}{\text{chr} - \cos \tau} \cdot e^{-t\delta} \quad \text{for } \delta > 0$$

$$\hat{\phi} = 1 + \frac{1}{r} \cdot \frac{\text{shr}}{\text{chr} - \cos \tau} \cdot f(r)$$

Then $\hat{\phi}$ is an end-periodic function and $\tilde{\phi} = \hat{\phi} + (\tilde{\phi} - \hat{\phi})$. We put $\nabla_{x_i} = \nabla_i$ for $i=1,2,3$. By a direct calculation

$$\nabla_i \log \tilde{\phi} = \frac{e^{-t\delta}}{\tilde{\phi}} \cdot \frac{x_i}{r^2(\text{chr} - \cos \tau)} \cdot \left(-\frac{\text{shr}}{r} + \frac{1 - \text{chr} \cos \tau}{\text{chr} \cos \tau} - t' \delta \text{shr} \right)$$

We denote by G_i the factor $\frac{x_i}{r^2(\text{chr} - \cos \tau)}$ and by $G^\#$ the factor $\left(-\frac{\text{shr}}{r} + \frac{1 - \text{chr} \cos \tau}{\text{chr} \cos \tau} - t' \delta \text{shr} \right)$. By further calculations

$$\nabla_r \log \tilde{\phi} = -\frac{1}{\tilde{\phi}} \cdot \frac{\sin \tau \text{shr}}{r(\text{chr} - \cos \tau)^2} \cdot e^{-t\delta}$$

The gauge potential is given by

$\tilde{A}_i = \sqrt{-1} \bar{\sigma}_{ij} \nabla_j (\log \tilde{\phi})$, where $\bar{\sigma}_{ij} = (1/4\sqrt{-1})[\sigma_i, \sigma_j]$ for $i, j = 1, 2, 3$ and $\bar{\sigma}_{i4} = -\frac{1}{2}\sigma_i$, (c.f.[3] and Jackiw, R., Nohl, C., Rebbi, C., Conformal properties of pseudo particle configurations, Phys. Review D 15, 8 (1977)). To get the curvature we need the following formulas,

$$\begin{aligned} \nabla_j \nabla_i \log \tilde{\phi} &= -\frac{1}{\tilde{\phi}^2} e^{-2t\delta} (G_j \cdot G^\#)(G_i \cdot G^\#) + \frac{1}{\tilde{\phi}} \nabla_j \nabla_i \tilde{\phi} \\ \nabla_j \nabla_i \tilde{\phi} &= e^{-t\delta} \left\{ \left[-\frac{t' \delta x_j}{r} G_i + \frac{\delta_{ij}}{r^2(\text{chr} - \cos \tau)} - \frac{2x_i x_j}{r^4(\text{chr} - \cos \tau)} - \frac{x_i x_j}{r^3} \cdot \frac{\text{shr}}{(\text{chr} - \cos \tau)^2} \right] G^\# \right. \\ &\quad \left. + \left[\frac{x_j \text{shr}}{r^2} - \frac{x_j \text{chr}}{r^2} - \frac{\text{shr} \cos \tau}{\text{chr} - \cos \tau} \cdot \frac{x_j}{r} - \frac{(1 - \text{chr} \cos \tau) \text{shr}}{(\text{chr} - \cos \tau)^2} \cdot \frac{x_j}{r} - \frac{t'' \delta x_j \text{shr}}{r} - \frac{x_j t' \delta \text{chr}}{r} \right] G_i \right\} \end{aligned}$$

$$\begin{aligned}\nabla_\gamma \nabla_i \tilde{\phi} &= e^{-i\delta} \left(\frac{-x_j \sin \tau}{r^2 (\text{chr} - \cos \tau)^2} G^\# + G \cdot \frac{\sin^2 r \sin \tau}{(\text{chr} - \cos \tau)^2} \right) \\ \nabla_\gamma \nabla_\gamma \log \tilde{\phi} &= \nabla_\gamma \left(\frac{\nabla_\gamma \tilde{\phi}}{\tilde{\phi}} \right) = -\frac{1}{\tilde{\phi}^2} (\nabla_\gamma \tilde{\phi})^2 + \frac{1}{\tilde{\phi}} \nabla_\gamma \nabla_\gamma \tilde{\phi} \\ \nabla_\gamma \nabla_\gamma \tilde{\phi} &= e^{-i\delta} \cdot \frac{\text{shr}}{r} \cdot \frac{\text{chr} \cos \tau - \sin^2 \tau - 1}{(\text{chr} - \cos \tau)^2}\end{aligned}$$

Since $\phi \doteq 0$ as $r \geq 1$, we obtain approximately the difference between our potential and H-S's in [3]:

$$\nabla_i \log \tilde{\phi} : e^{-i\delta} \cdot \frac{x_i t' \delta \text{shr}}{r^2 (\text{chr} - \cos \tau)}$$

$$\nabla_j \nabla_i \log \tilde{\phi} : e^{-2i\delta} \{ 2G_i G^\# G_j (t' \delta \text{shr}) - G_i G_j (t' \delta \text{shr})^2 \} + e^{-i\delta} \frac{x_i t' \delta}{r} G_i G^\# + \frac{\delta x_j (t'' \text{shr} + t' \text{chr})}{r} G_i$$

Therefore $\tilde{A} = \hat{A} + (\tilde{A} - \hat{A}) \in \mathcal{A}(2\delta)$ for any δ such that $0 < 2\delta < \delta_*$, where \tilde{A} and \hat{A} denote the connections derived from $\tilde{\phi}$ and $\hat{\phi}$.

Now we consider an electric field $E: R \rightarrow R^3 \cup \{\infty\}$ which is by definition linear and the field of a single charge has the properties:

1) $E \rightarrow 0$ at ∞ , 2) $E \rightarrow \infty$ at the source, 3) E is spherically symmetric (c.f.[2]). Then we have

LEMMA. The map $(\nabla_i \log \tilde{\phi}): C_1(R^3) \rightarrow \Omega^3_1(S^3)$ gives an electric field.

PROOF. As $r \rightarrow \infty, \phi \rightarrow 1, e^{-i\delta} \rightarrow 0, t'$ is bounded. Then $\nabla_i \log \tilde{\phi} \rightarrow 0$. As $r \rightarrow 0, \text{shr}/r \rightarrow 1, \text{chr} \rightarrow 1, e^{-i\delta} = 1, t' = 0$. Let τ to be zero. Then $(-\text{shr}/r - 1) \rightarrow -2$. By the fact $(x_1/r^2)^2 + (x_2/r^2)^2 + (x_3/r^2)^2 \rightarrow \infty$ we have $\|(\nabla_i \log \tilde{\phi})\| \rightarrow \infty$. Now clearly $(\nabla_i \log \tilde{\phi})$ is spherically symmetric in R^3 . Thus, we obtain the lemma.

Next we consider homotopic deformation,

$$\tilde{\phi}_{(s)}(\delta) = 1 + \frac{s}{r} + \frac{(1-s)\text{shr}}{r(\text{chr} \cos \tau)} \cdot e^{-i\delta}, \quad 0 \leq s \leq 1.$$

Then $\tilde{\phi}(\delta)$ is homotopic to $\tilde{\phi}_{(1)} = 1 + 1/r$ and so $\nabla \log \tilde{\phi}(\delta)$ is homotopic to $\nabla \log \tilde{\phi}_{(1)}$, which is self-dual in R^4 . In the same way we can see that $\nabla \log \tilde{\phi}(\delta)$ is homotopic to $\nabla \log \hat{\phi}$ which is trivial on $\text{End}M$. Now we consider k -instantons. For this purpose we consider the functions

$$\tilde{\phi}_k(\delta) = 1 + \sum_{i=1}^k \frac{1}{r_i} \cdot \frac{\text{shr}_i}{\text{chr}_i - \cos \tau} \cdot e^{-i\delta}$$

$$\hat{\phi}_k = 1 + \sum_{i=1}^k \frac{1}{r_i} \cdot \frac{\text{sh} r_i}{\text{ch} r_i - \cos \tau} \cdot f(r_i)$$

where r_i denotes the distance from a point to i -th base point in R^3 , $i = 1, 2, \dots, k$. A set of k -distinct base points can be regarded as an element of the configuration space $C_k(R^3)$. We denote by A the connection which is obtained from $\hat{\phi}_k$. The space R^3 is deformable onto the unit open disc by a homotopy

$$(1-s)x + \frac{2s \text{Tan}^{-1} \|x\|}{\|x\| \pi} \cdot x \quad \text{for } 0 \leq s \leq 1 \text{ and } x \neq 0,$$

where the origin in R^3 is fixed. Thus we can assume that k -distinct points lies in the unit open disc in R^3 . Then by the construction in Remark 2 in [1] we have a 1-form a such that $A+a$ is self-dual where the connection A has a compact support. Therefore the 1-form a also has a compact support. For $g \in \mathcal{G}'_k(\delta)$, by making use of the homotopy $g^{-1}(A + (1-s)a)g + g^{-1}dg$, $0 \leq s \leq 1$, we can see that the homotopy gives a homotopy in the space $\mathcal{B}'_k(\delta) = \mathcal{A}_k(\delta) / \mathcal{G}'_k(\delta)$. Then the class $[A+a]$ is homotopic to the class $[A]$. Thus the gauge potential $\nabla \log(\tilde{\phi}_k)$ gives an element of $\mathcal{M}'_k(\delta)$.

3. Proof of Main theorem

We prove the theorem by making use of a modified Atiyah-Jones diagram [2]. We denote by B_k and M_k the moduli space of connections and self-dual connections on an $SU(2)$ bundle over R^4 with topological charge k respectively. By the consideration in Section, $\log \tilde{\phi}(\delta)$ is homotopic to $\log \tilde{\phi}_{(1)}$. Then by the lemma (3, 6) in [2] we have a homotopy-commutative diagram

$$\begin{array}{ccccc}
 C_k(R^3) & & \xrightarrow{\nabla \log \tilde{\phi}_k(\delta)} & & \Omega^3_k(S^3) \\
 & \searrow & & \nearrow & \\
 & & M_k & \xrightarrow{\cong} & B_k \\
 i \downarrow & & & & \nwarrow \lambda_k \\
 C_k(R^4) & \nearrow & & \longrightarrow & \Omega^4_k(S^4)
 \end{array}$$

where λ_k is the map (3.4) in [2].

We denote by $\Omega^{1,2}_k(S^3)$ the set of based maps from the space $S^1 \times S^2$ to S^3 of degree k . For a map $p: S^1 \times S^2 \rightarrow S^3$ we define a map $\hat{p}: S^1 \times S^2 \rightarrow S^3$ by

$$\hat{p}(t, x) = p(t, x_0)^{-1} p(t, x) p(t_0, x)^{-1}$$

Thus we obtain the following homotopy-commutative diagram:

where i and γ denote the inclusion maps and h denotes the composite map of $P \cdot C$ and a homotopy inverse $\Omega^3_k \rightarrow B_k$. The commutativity in the lower part follows from the consideration in the section 2. By the theorem due to G•Segal ([5]) the induced homomorphism

is an isomorphism for $k \gg q$. The homotopy type of $\Omega_k^3(S^3)$ is independent of k .

Then by the proposition (A.1) in [6], $H_q(C_k(R^3)) \rightarrow H_q(\Omega^3_k(S^3))$ is an isomorphism for $q \leq [k/2]$. Therefore the homomorphism

$$(P \cdot C \cdot \gamma)_* : H_g(\mathcal{M}'_k(\delta)) \rightarrow H_g(\Omega^3_k(S^3))$$

is surjective for $q \leq [k/2]$. Thus we have proved the theorem.

REMARK. By making use of a diffeomorphism

$$R^3 \times S^1 \ni (x, y, z, \theta) \rightarrow (x, y, e^z \cos \theta, e^z \sin \theta) \in R^4 - R^2 \cong S^4 - S^2,$$

we obtain a compactification of the space up to diffeomorphism. But I do not know a conformal compactification without singularities ([4]).

APPENDIX. Proof of the proposition in the section one.

Firstly I should remark that the manifold $M = S^1 \times R^3$ has been considered as an end-periodic manifold

$$M' = S^1 \times D^3_{3/2} \cup (S^1 \times S^2 \times (1, 3)) \cup (S^1 \times S^2 \times (2, 4)) \cup \dots \quad (2.[1])$$

The space $S^1 \times S^2 \times [1, \infty)$ admits the pull-back metric via π of the product metric on the space $S^1 \times S^2 \times S^1$. By making use of the cut off function f in the section 2, we connect the natural metric g_0 in the space $S^1 \times D^2_{3/2}$ with the metric g_1 on the $\text{End}M$, and we obtain a metric on the manifold M'

$$g = f(r)g_0 + (1 - f(r))g_1.$$

Then the restriction of the metric g over $\text{End}M$ is induced from the conformally flat metric g_1 on the manifold Y . Thus we obtain an end-periodic metric on the manifold M' .
